

AquaGuard — Pump Check-Valve Circuit Diagram

One check valve per pump, installed right at the pump's own outlet barb — each pump gets its own, not shared, not further downstream

How it works: ① Pump OFF → spring holds the poppet shut against its seat — sealed, no path through. ② Pump ON → water pressure compresses the spring, lifts the poppet, water flows freely. ③ Pump OFF again → spring snaps shut instantly, before gravity/siphon pressure can push water backward through it.
